Point Pattern Analysis

HES 505 Fall 2023: Session 18

Matt Williamson

Objectives

- Define a point process and their utility for ecological applications
- Define first and second-order Complete Spatial Randomness
- Use several common functions to explore point patterns
- Leverage point patterns to interpolate missing data

What is a point pattern?

- *Point pattern*: A **set** of **events** within a study region (i.e., a *window*) generated by a random process
- Set: A collection of mathematical events
- **Events**: The existence of a point object of the type we are interested in at a particular location in the study region
- A marked point pattern refers to a point pattern where the events have additional descriptors

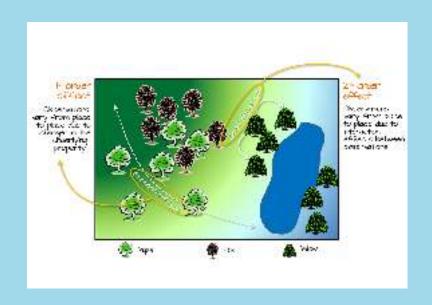

Some notation:

- S: refers to the entire set
- s_i denotes the vector of data describing point s_i in set S
- $\#(S \subseteq A)$ refers to the number of points in S within study area A

Requirements for a set to be considered a point pattern

Describing Point Patterns

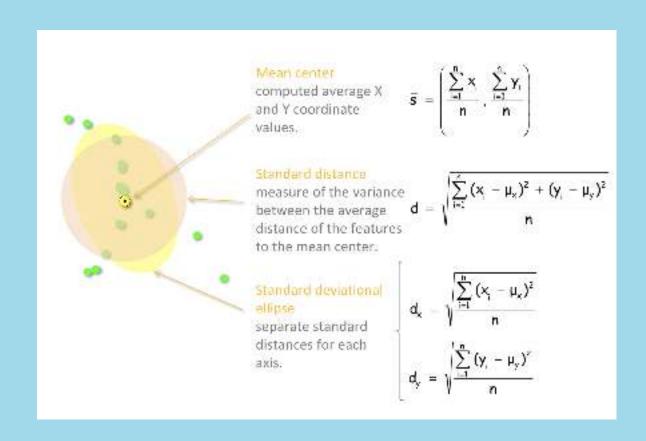

- *Density-based metrics*: the # of points within area, a, in study area A
- *Distance-based metrics*: based on nearest neighbor distances or the distance matrix for all points
- *First order* effects reflect variation in **intensity** due to variation in the 'attractiveness' of locations
- Second order effects reflect variation in **intensity** due to the presence of points themselves

from Manuel Gimond

Centrography

- *Mean center*: the point, **s**, whose coordinates are the average of all events in the pattern
- *Standard distance*: a measure of the dispersion of points around the *mean center*
- *Standard ellipse*: dispersion in one dimension

From Manuel Gimond

Analyzing Point Patterns

- Modeling random processes means we are interested in probability densities of the points (first-order;density)
- Also interested in how the presence of some events affects the probability of other events (second-order; distance)
- Finally interested in how the attributes of an event affect location (marked)
- Need to introduce a few new packages (spatstat and gstat)

Density based methods

• The overall *intensity* of a point pattern is a crude density estimate

$$\hat{\lambda} = \frac{\#(S \in A)}{a}$$

* Local density = quadrat counts

40	°1	0	1 0	2 º
0 2	0030	0 0 0 0	1	2°
zº.	ි ය ව	6 0		2
် 3	0	ം ഉ ഗ 3 ഗ	1 0	2 a
3	° 1	2	o 2º	10

Analyzing Point Patterns

Kernel Density Estimates (KDE)

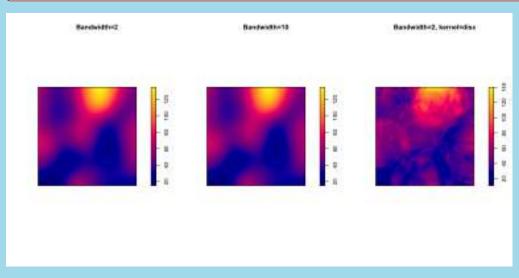

$$\hat{f(x)} = \frac{1}{nh_x h_y} \sum_{i=1}^{n} k\left(\frac{x - x_i}{h_x}, \frac{y - y_i}{h_y}\right)$$

- Assume each location in s_i drawn from unknown distribution
- Distribution has probability density $f(\mathbf{x})$
- Estimate $f(\mathbf{x})$ by averaging probability "bumps" around each location
- Need different object types for most operations in R (as ppp)

Kernel Density Estimates (KDE)

- h is the bandwidth and k is the kernel
- We can use stats::density to explore
- **kernel**: defines the shape, size, and weight assigned to observations in the window
- bandwidth often assigned based on distance from the window center

```
1 x <- rpoispp(lambda =50)
2 K1 <- density(x, bw=2)
3 K2 <- density(x, bw=10)
4 K3 <- density(x, bw=2, kernel="disc")</pre>
```

Choosing bandwidths and kernels

- Small values for h give 'spiky' densities
- Large values for h smooth much more
- Some kernels have optimal bandwidth detection
- tmap package provides additional functionality

Second-Order Analysis

Second-Order Analysis

- KDEs assume independence of points (first order randomness)
- Second-order methods allow dependence amongst points (second-order randomness)
- Several functions for assessing second order dependence (K, L, and G)

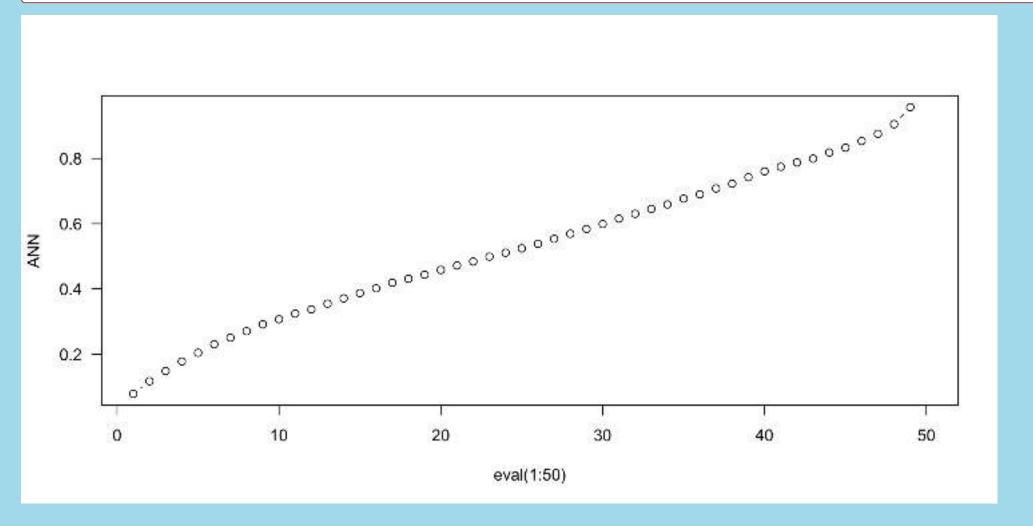

Distance based metrics

- Provide an estimate of the *second order* effects
- Mean nearest-neighbor distance:

$$\hat{d_{\min}} = \frac{\sum_{i=1}^{m} d_{\min}(s_i)}{n}$$

Nearest-neighbor distance

```
1 ANN <- apply(nndist(x, k=1:50),2,FUN=mean)
2 plot(ANN ~ eval(1:50), type="b", main=NULL, las=1)</pre>
```

- Nearest neighbor methods throw away a lot of information
- If points have independent, fixed marginal densities, then they exhibit *complete*, spatial randomness (CSR)
- The *K* function is an alternative, based on a series of circles with increasing radius

$$K(d) = \lambda^{-1} E(N_d)$$

• We can test for clustering by comparing to the expectation:

$$K_{CSR}(d) = \pi d^2$$

• if $k(d) > K_{CSR}(d)$ then there is clustering at the scale defined by d

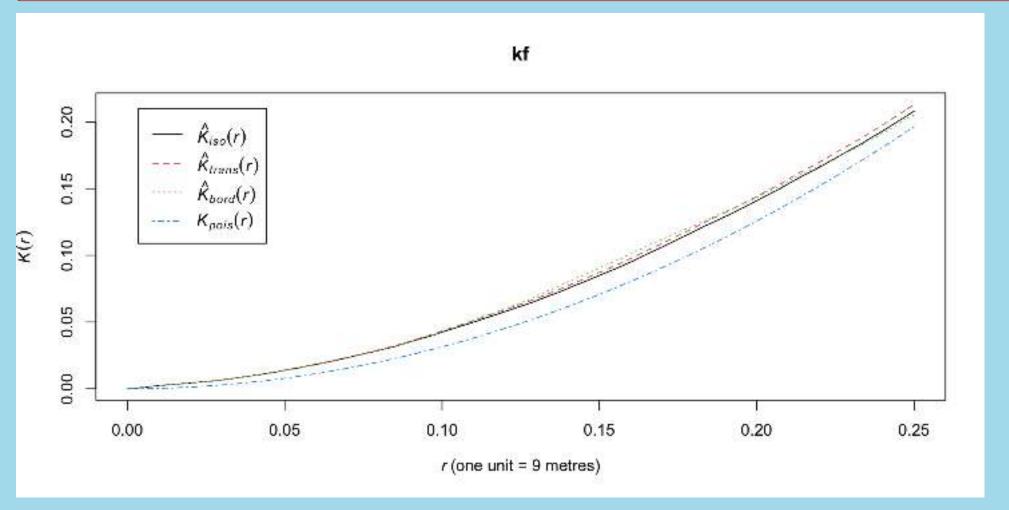

- When working with a sample the distribution of K is unknown
- Estimate with

$$\hat{K}(d) = \hat{\lambda}^{-1} \sum_{i=1}^{n} \sum_{j=1}^{n} \frac{I(d_{ij} < d)}{n(n-1)}$$

where:

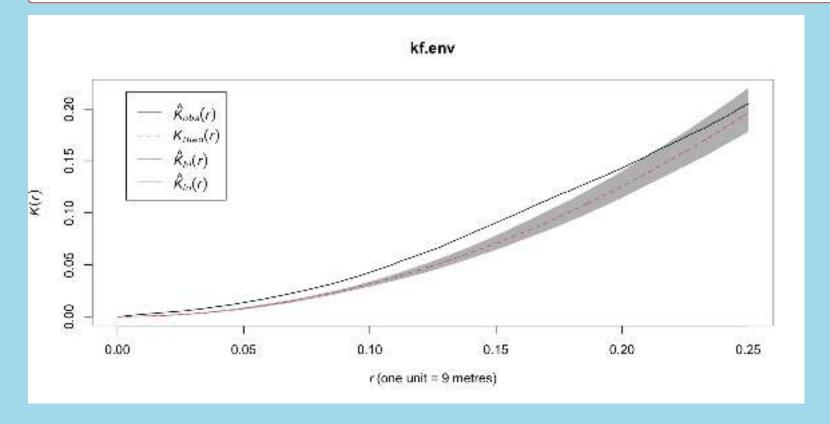

$$\hat{\lambda} = \frac{n}{|A|}$$

```
1 kf <- Kest(bramblecanes, correction-"border")
2 plot(kf)</pre>
```

accounting for variation in d

```
1 kf.env <- envelope(bramblecanes, correction="border", envelope = FALSE, ver
2 plot(kf.env)</pre>
```

Other functions

- L function: square root transformation of K
- G function: the cummulative frequency distribution of the nearest neighbor distances
- F function: similar to G but based on randomly located points
